Scope

In this session we will explore basic manipulations of variables.

- ▶ Assigning a value to a variable
- ▶ Basic operations on numbers

Slide With Code

Convention:

- ▶ Gray boxes: commands to type in RStudio **Console** (bottom-left panel).
- ▶ White boxes: the result you should obtain.

Example: create a variable named ***a***, assign the value **27** to this variable, and ***print*** the result.

```
a <- 27  
print(a)
```

```
## [1] 27
```

Vectors of values

The simplest data structure in R is a vector. In the previous example, the variable *a* was actually a vector with a single value.

Example: create a variable named *three.numbers*, and initialize it with a vector with values *27*, *12* and *3000*.

Tips: - variable names can comprize several parts, separated by dots.
- the function `c()` combines several values into a vector

```
three.numbers <- c(27,12,3000)
print(three.numbers)
```

```
## [1]    27    12 3000
```

Series

The simple way to create a series of numbers. The column operator permits to generate all integer values between two limits.

```
x <- 0:14  
print(x)
```

```
##      [1]  0  1  2  3  4  5  6  7  8  9 10 11 12 13 14
```

Computing with vectors

R handles vectors in a very convenient way. An operation on a vector applies to all its elements.

```
x <- 1:10 # Define a series from 1 to 10  
print(x)
```

```
## [1] 1 2 3 4 5 6 7 8 9 10
```

```
y <- x^2 # Compute the square of each number  
print(y)
```

```
## [1] 1 4 9 16 25 36 49 64 81 100
```

Scatter plot

```
x <- -10:10  
y <- x^2  
plot(x,y)
```

Line plot

```
x <- -10:10  
y <- x^2  
plot(x,y, type="l")
```

Variables can also contain strings

```
# The # symbol allows to insert comments in R code  
  
# Define a vector named "whoami", and  
# containing two names  
whoami <- c("Denis", "Siméon")  
print(whoami) # Comment at the end of a line
```

```
## [1] "Denis" "Siméon"
```

String concatenation

```
# Define a vector named "names", and  
# containing two names  
whoami <- c("Denis", "Siméon")  
  
# Paste the values of a vector of string  
print(paste(sep=" ", whoami[1], whoami[2]))
```

```
## [1] "Denis Siméon"
```

Carl's preferred distribution

The function `dpois()` computes the Poisson **density**, i.e. the probability to observe **exactly** x successes in a series of independent trials with equal probability.

The Poisson distribution is defined by a single parameter: the expected number of successes λ (read “lambda”).

$$P(X = x) = \frac{e^{-\lambda} \lambda^x}{x!}$$

```
x <- 0:14    # Define the X values from 0 to 14
y <- dpois(x, lambda = 2.5) # Poisson density
print(y)    # Check the result
```

Plotting the Poisson distribution

```
x <- 0:14    # Define the X values from 0 to 14  
y <- dpois(x, lambda = 2.5) # Poisson density  
plot(x,y)    # Check the result
```

Getting help for R functions

Need help? Type `help()`.

```
help(plot)
```

A question? Type `?`

```
?plot
```

Result: R displays the help message for the function `dpois()`.

Exercise: improve Poisson density plot

1. Do not (yet) look the next slide.
2. Read the help page for the `dpois()` function.
3. draw a plot that provides a didactic illustration of the Poisson density.

Improve the plot: type = histogram

```
x <- 0:14  
lambda <- 2.54  
y <- dpois(x, lambda)  
plot(x,y, type="h")
```

Improve the plot: Add a title

```
plot(x,y, type="h", lwd=5, col="blue",  
     main="Poisson density")
```

Improve the plot: define axis labels

```
plot(x,y, type="h", lwd=5, col="blue",  
     main="Poisson density",  
     xlab="x = number of successes",  
     ylab="P(X=x)")
```

Improve the plot: add a legend

```
plot(x,y, type="h", lwd=5, col="blue",  
     main="Poisson density",  
     xlab="x = number of successes",  
     ylab="P(X=x)")  
legend("topright", paste("lambda =", lambda))
```

Poisson: a family of curves

Exercice: explore the properties of the Poisson density function, by changing the range of x values, and the λ parameter.
